## "Exhibit A"

## Supercoiling

supercoiling

(Science: molecular biology) In <u>circular DNA</u> or closed <u>loops</u> of <u>dNA</u>, <u>twisting</u> of the DNA about its own <u>axis changes</u> the <u>number</u> of <u>turns</u> of the <u>double helix</u>.

If <u>twisting</u> is in the <u>opposite</u> direction to the <u>turns</u> of the <u>double helix</u>, i.e. Anticlockwise, the <u>dNA strands</u> will either have to unwind or the whole <u>structure</u> will <u>twist</u> or supercoil termed <u>negative</u> supercoiling.

If <u>twisting</u> is in the same direction as the <u>helix</u>, clockwise, which <u>winds</u> the <u>dNA</u> up more tightly, <u>positive</u> supercoiling is generated. DNA that shows no supercoiling is said to be relaxed

Supercoiling in <u>circular DNA</u> can be detected by <u>electrophoresis</u> because supercoiled <u>dNA migrates</u> faster than <u>relaxed DNA</u>. Circular DNA is commonly <u>negatively</u> supercoiled and the DNA of <u>eukaryotes</u> largely <u>exists</u> as supercoils <u>associated</u> with <u>protein</u> in the <u>nucleosome</u>. The <u>degree</u> of supercoiling can be altered by <u>topoisomerases</u>.
